

Measuring & Influencing Resilience of Adapting Flow Networks

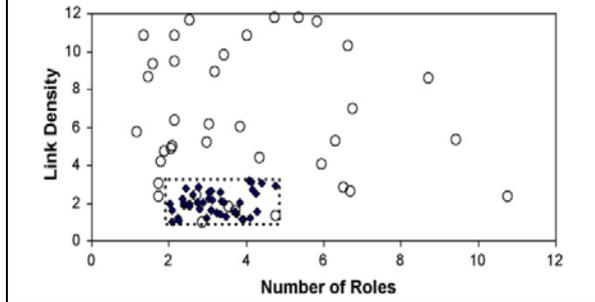

Walt Beyeler, Eric Vugrin, Steve Verzi,
Geoff Forden, Munaf Aamir,
Chris Lamb, Sasha Outkin

Presentation to Sandia National Laboratories' Complex Systems Advisory Panel

- This presentation describes a model designed to study the effects of adaptive network growth on the network's resilience, summarizing:
 - Research questions
 - Model formulation
 - Initial results

Understanding Connections between Network Structure and Performance

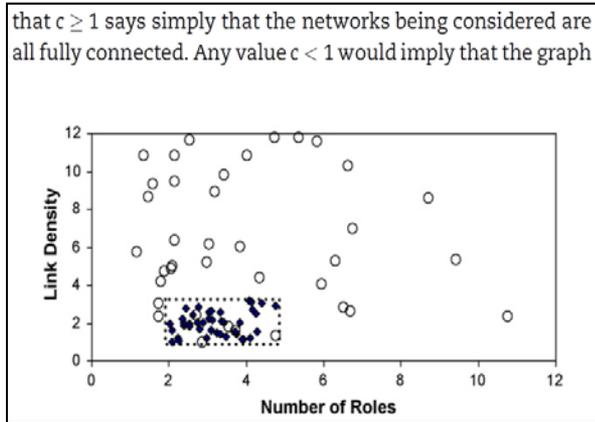

that $c \geq 1$ says simply that the networks being considered are all fully connected. Any value $c < 1$ would imply that the graph

From Ulanowicz et al., *Eco. Compl.* 6 pp 27-36

- Trophic (and other) networks are topologically intermediate between minimally and richly connected
- Maybe this reflects a compromise between being efficient as a system and needing to survive local disruptions
- Maybe structure is an indicator of resilience

Understanding Connections between Network Structure and Performance

From Ulanowicz et al., Eco. Compl. 6 pp 27-36

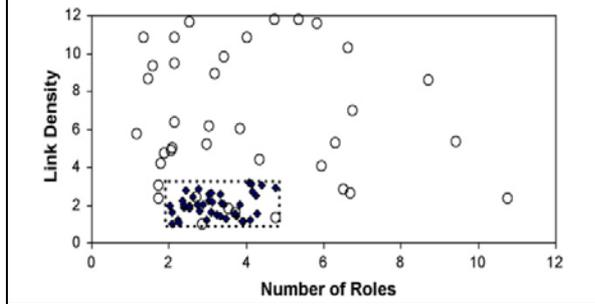

- Trophic (and other) networks are topologically intermediate between minimally and richly connected
- Maybe this reflects a compromise between being efficient as a system and needing to survive local disruptions
- Maybe structure is an indicator of resilience

Questions:

- Can local adaptation accomplish this tradeoff?
- Does it leave a signature in the topology?
- Is it a (systemically) good tradeoff?
... can it be made so?
- Can structural measures predict performance resilience?
 - Against historical shocks?
 - Against larger shocks?

Flow and Growth Process Models

Each node i has a potential s_i

Each link ij has a capacity c_{ij}

Flow rates are limited by a (directed) capacity associated with each link, c_{ij} . Assuming $s_i > s_j$, the flow from node i to node j is given by:

$$q_{ij} = c_{ij} f((s_i - s_j)k_{ij}) \quad (1)$$

In equilibrium, the net flow at each node i is 0, including any internal sources (q_{si}) or sinks (d_i):

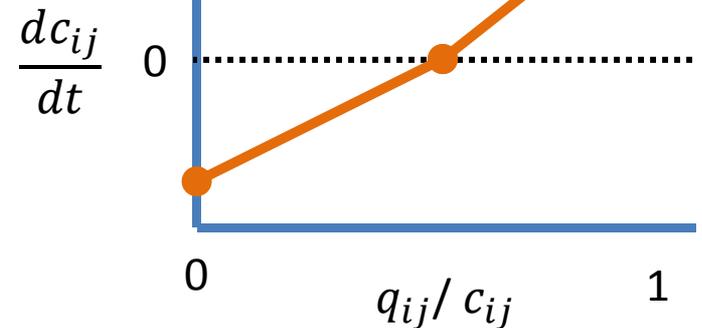

$$\sum_j q_{ji} + q_{si} - d_i = 0 \quad \forall i \quad (3)$$

The equilibrium solution $\{\hat{s}_i\}$ is obtained by solving equations (1-3).

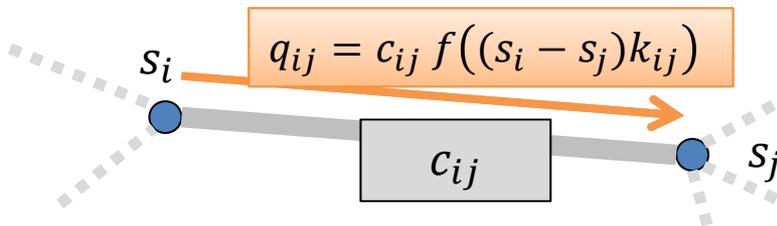

where k_{ij} is a conductance parameter and the function $f(x)$ models linear resistance as $x \rightarrow 0$ and enforces the capacity limit for large x :

$$f(x) \equiv 1 - e^{-x} \quad (2)$$

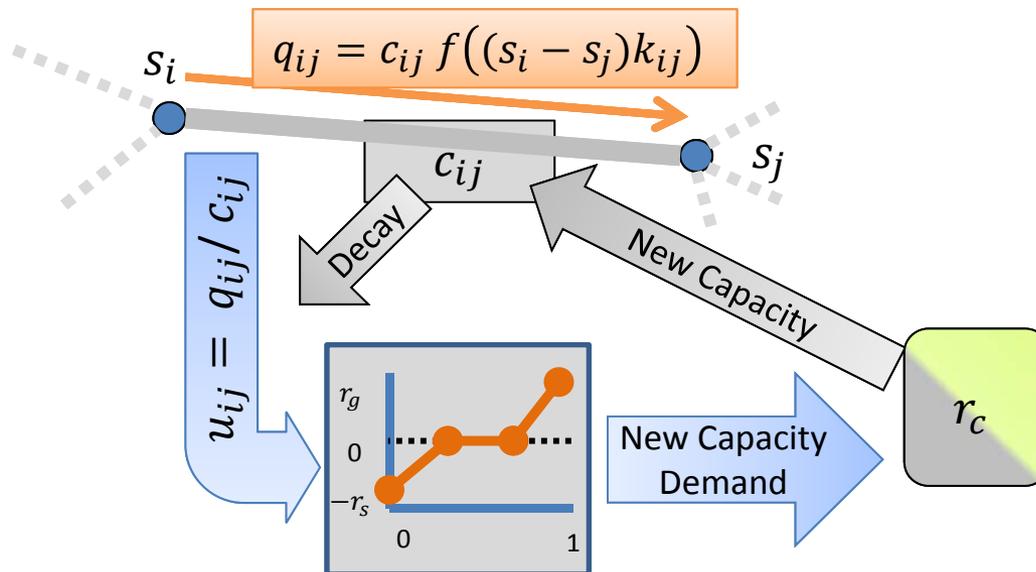

Network adapts by changing link capacities in response to utilization:

Assessing Resilience to Extraordinary Disruptions

Assessing Resilience to Extraordinary Disruptions

Assessing Resilience to Extraordinary Disruptions

Summary

- Network structure can reflect an adaptive response, balancing requirements for good nominal performance and resistance to disruption
- Whether this adaptation leads to a resilient system depends on ...
- We are using a simple model of a class of infrastructure systems to understand whether (or under what conditions) adaptation to small disruptions can confer resilience to big ones
- Initial results suggest that
 - The undisturbed system tends toward efficiency
 - Adaptation under disruption can improve performance compared to naïve systems
- Next:
 - Complete and publish an exploration of parameter space for this model
 - Explore application of the approach to other systems of interest having different driving processes and adaptive responses (human networks, communications systems, biological systems)
