What is an event?

- A segment of time at a given location that is perceived by an observer to have a beginning and an end

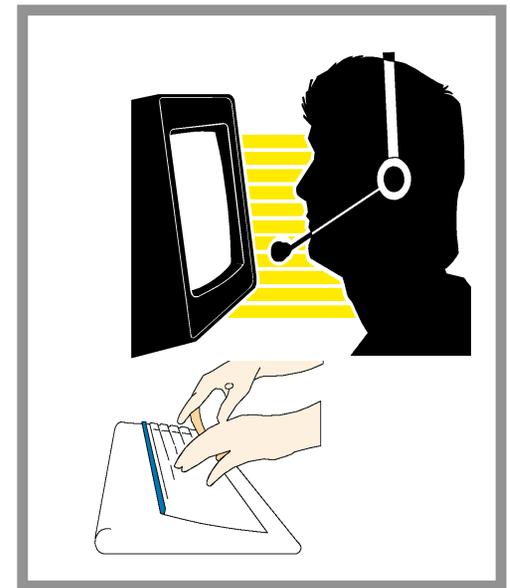

(Zacks & Tversky, 2001, Psych. Bull.)

Yes, but what sorts of events?

- Everyday, goal-directed activity
- Short (< 10 minutes)
- Examples:
 - Making a bed
 - Washing a car
 - Ironing a shirt

Experimental procedure

- Observers watch videos of others performing activities
- Tap a key to mark “natural and meaningful” events
- Vary event grain
 - Fine
 - Coarse

<interactive animation>

Event segmentation

- Reliable
 - Across individuals $P(\text{agree}) = .28$
 - Test-retest > year = .38 (Speer et al., 2003, CABN)
- Hierarchical organization of large-scale and small-scale events (Zacks, Tversky & Iyer, 2001, JEP: General)

Three questions about the neurophysiology of event perception

- Is segmentation a concomitant of normal perception?
- Does brain activity distinguish large from small events?
- What can the neuroanatomy tell us about how event parts are detected?

Functional MRI

- fMRI: Measures local changes in blood properties due to neural activity
- Good temporal resolution (2.16-2.36 s)
- Good spatial resolution (3.75 mm)

(Zacks, Braver, et al., 2001, Nat. Neuro.)

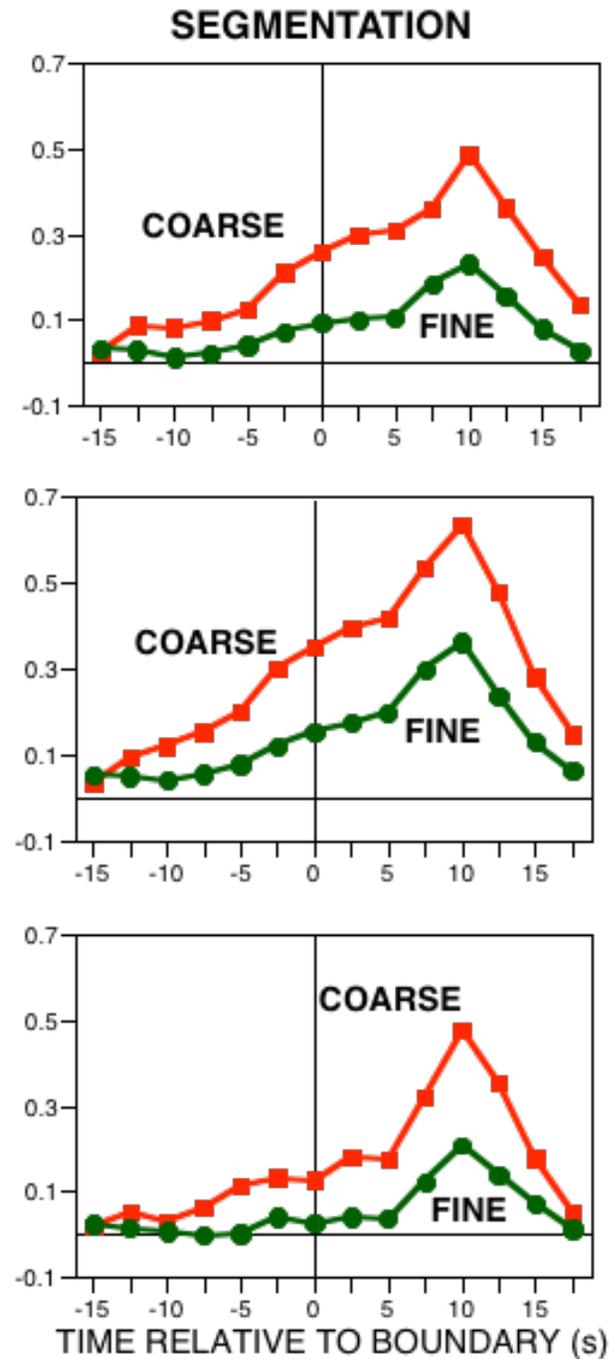

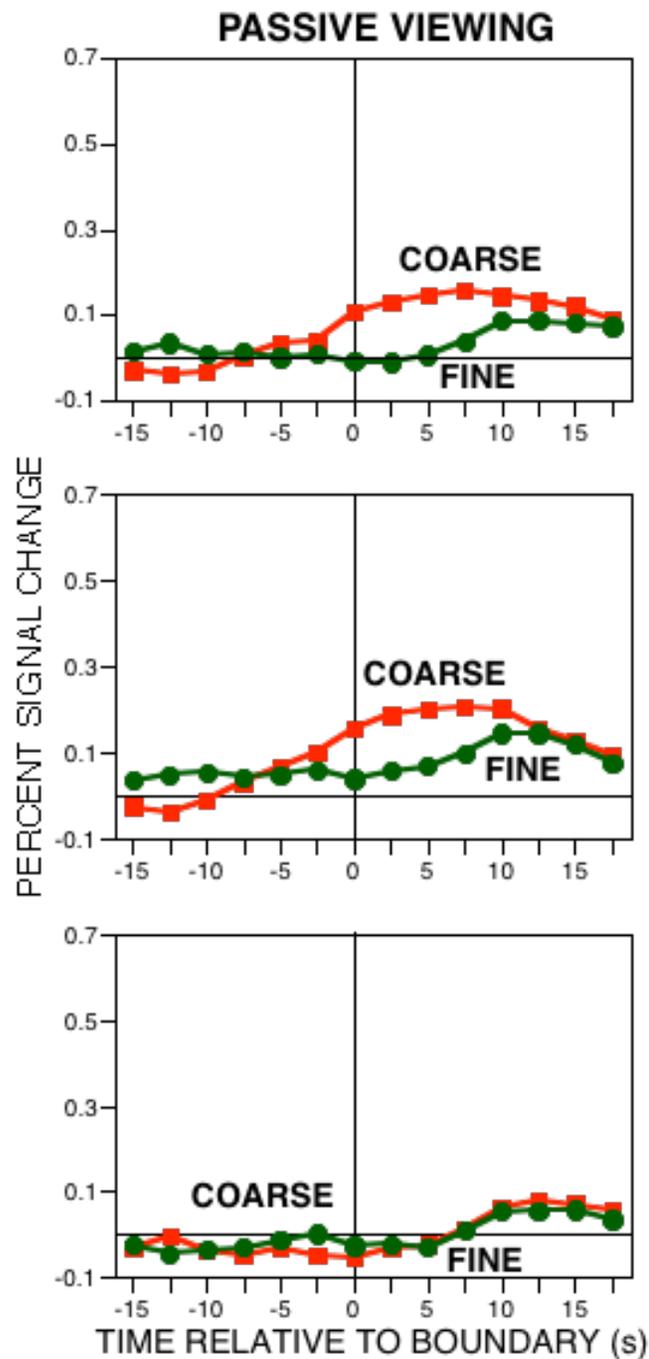

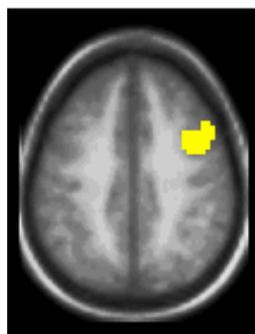

Key problem: How to observe without disturbing?

- Solution:
 - Use observers' event boundaries to define "trials."
 - Collect segmentation data after functional imaging.

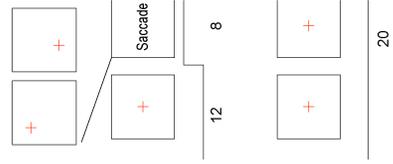

- Scans 1-4: passive viewing
- Training on **coarse** segmentation
- Scans 5-8: **coarse** segmentation
- Training on **fine** segmentation
- Scans 9-12: **fine** segmentation

MT+?

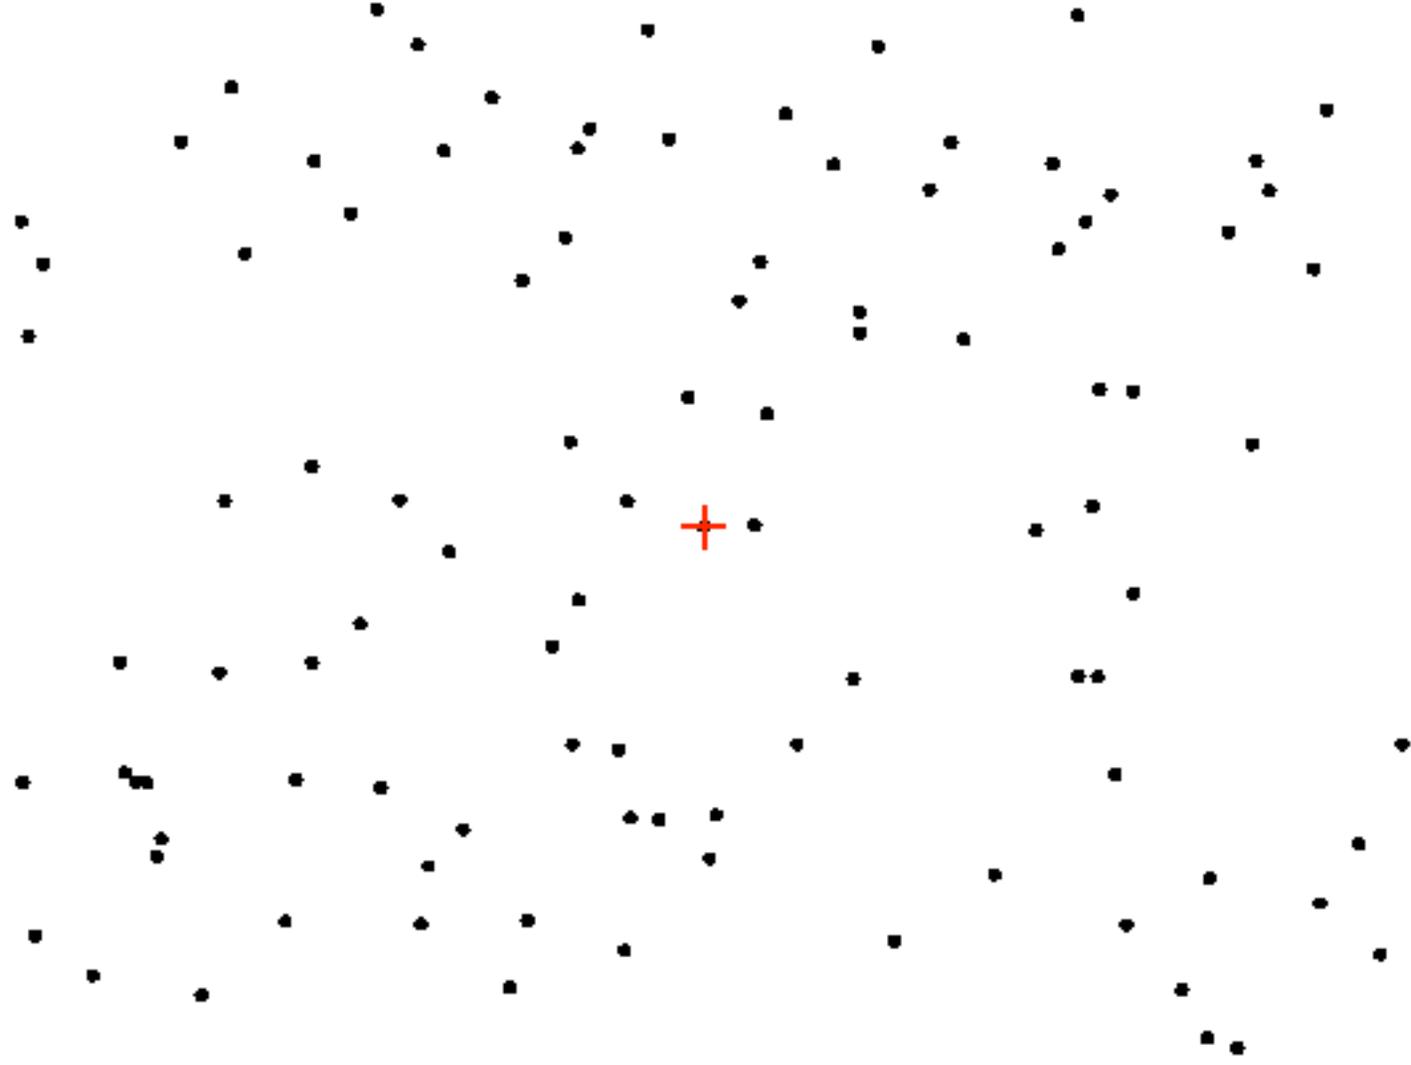

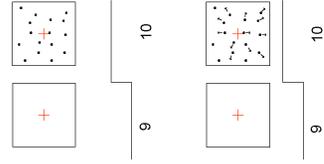

Premotor
Cortex

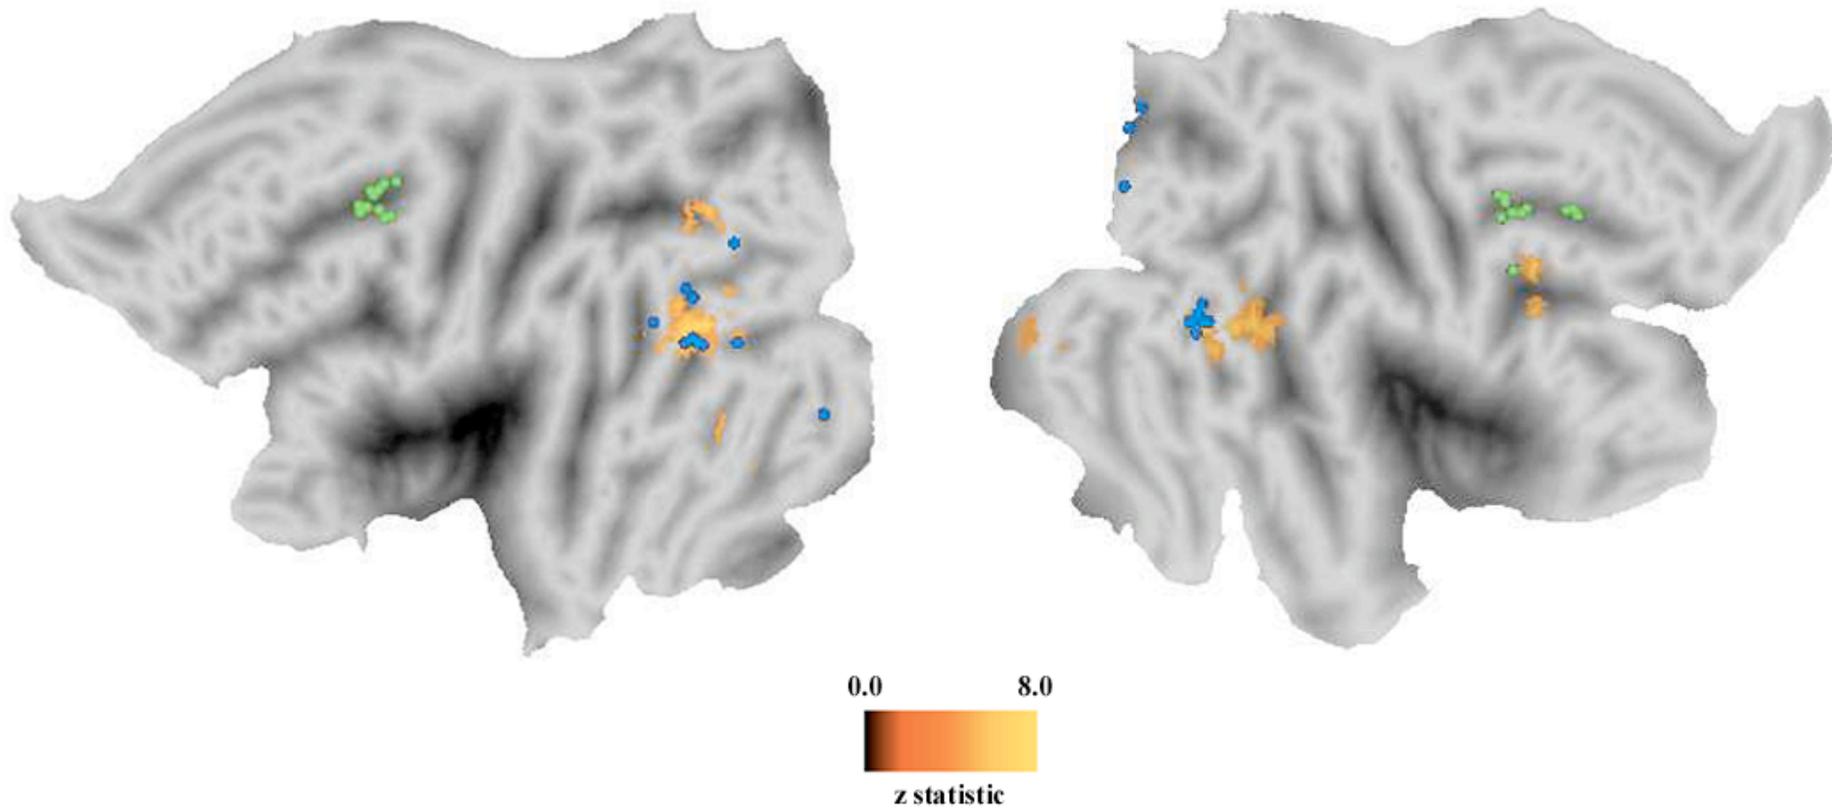

Localization S_c

Localization S_t

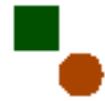

(Swallow et al., 2003, NeuroImage)

Neural processing

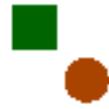

- Is event segmentation a concomitant of normal perception?
 - YES
- Does brain activity distinguish large from small events?
 - YES
- What can the neuroanatomy tell us about how event parts are detected?
 - Prominent activity in MT+
 - Motion processing?

Movement and segmentation

- How do people use motion information to encode activity?

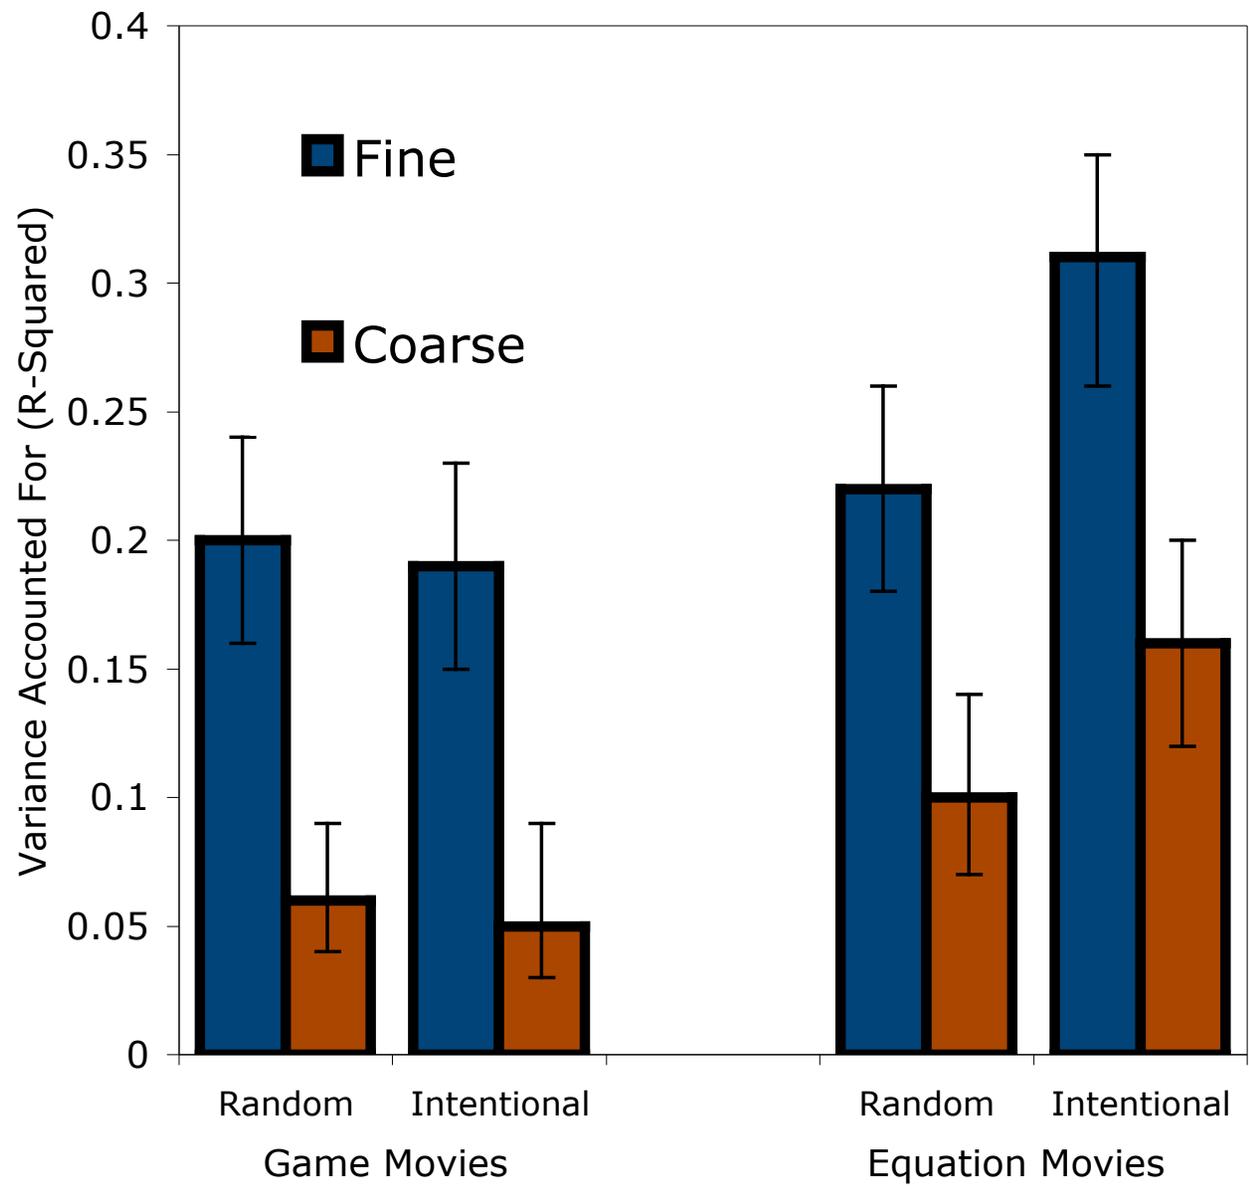

(Zacks, in press, Cognitive Science)

- Attribution manipulation
 - Intentional
 - Random
- Stimulus manipulation
 - Game
 - Equation

<interactive animation>

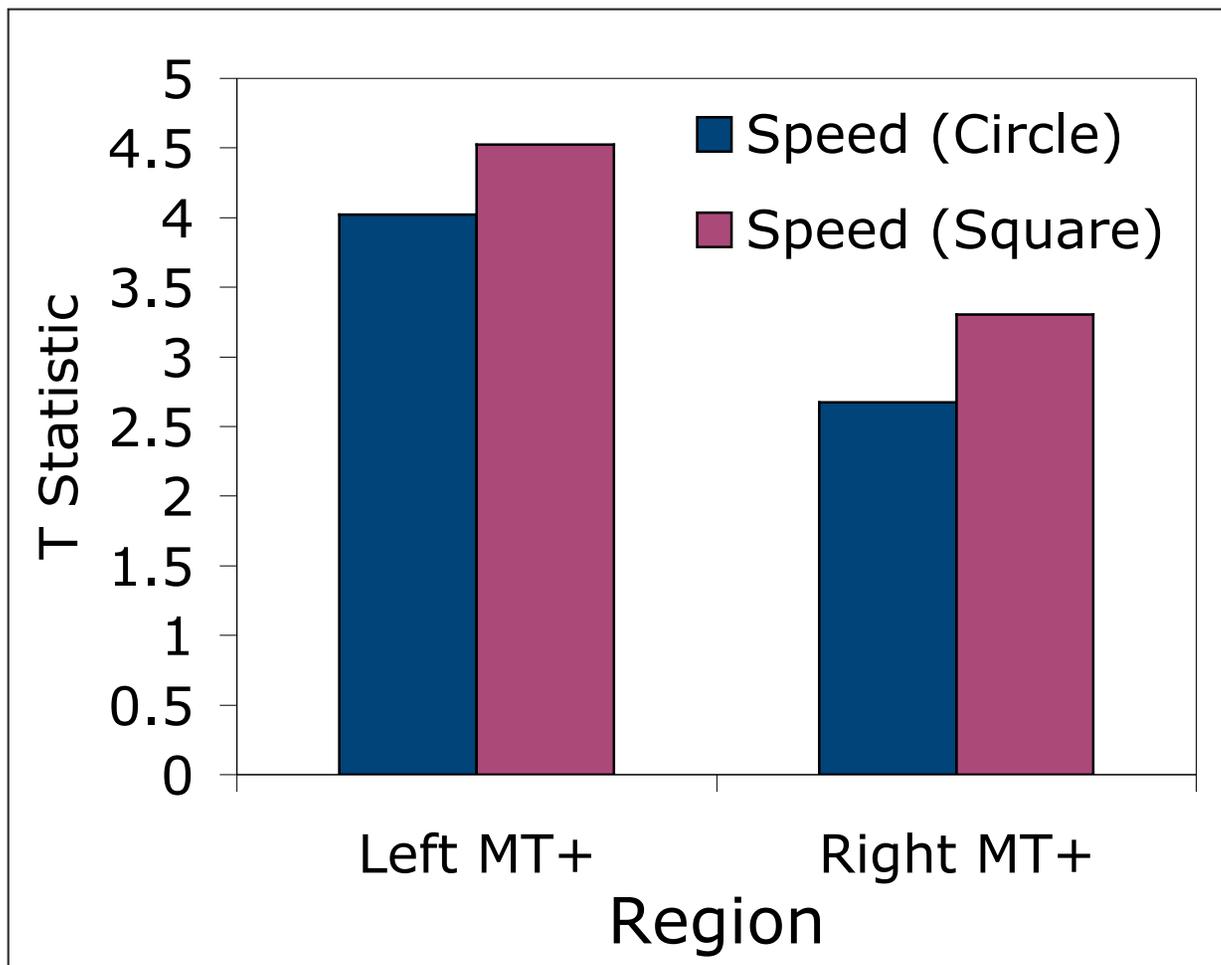

Movement and segmentation

- Movement information can be used to identify event boundaries
- When activity is intentional, something more is happening

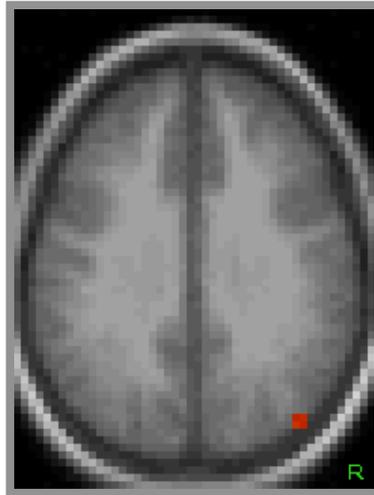

Functional MRI of Simple Animations

- Random animations
- Passive viewing during scanning
- MT+ localizer

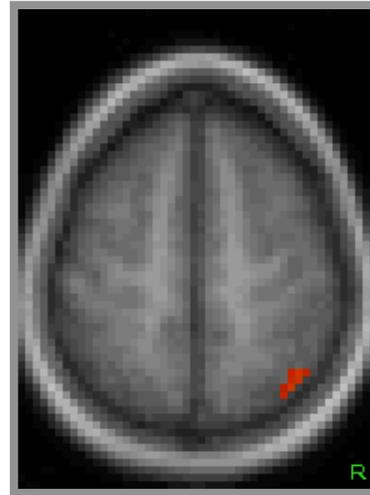

MT+ Correlated With Object Speed

Occipito-parietal Cortex Correlated With Object Acceleration

$z = 30$

$z = 51$

Conclusions

- Event segmentation is a reliable concomitant of normal perception
- Perceptual and neural processing distinguish large-scale and small-scale events
- The perception of event structure is related to
 - bottom-up processing of movement
 - top-down processing of goals, plans, and conventions
